## EXPECTATIONS

Vs

## REALITY

# Exploratory Data Analysis

---

Definition:

It refers to process of analyzing and examining dataset to summarize the main characteristics of the data.

Exploratory Data Analysis (EDA) refers to the process of visually and statistically summarizing, analyzing, and interpreting data sets in order to uncover patterns, trends, anomalies, and relationships within the data.

# Data Description

---

Examining and summarizing the main characteristics of the data using a variety of techniques, often visual and statistical.

Statistical summary: Calculating measures like mean, median, standard deviation, and quartiles to understand central tendencies and spread.

Visual summary: Creating charts and plots like histograms, box plots, and bar graphs to visualize the distribution of each variable.

Descriptive statistics such as measure of central tendency and variability are commonly used to summarize numerical data while frequency distribution and histogram are often used to summarize categorical data.

---

Check the structure of the dataset, the statistics, the missing values, the duplicates, the unique values of the categorical variables.

Understand the meaning and the distribution of the variables

Study the relationships between variables

To analyse how the dataset is organised, there are the following Pandas methods that can help you:

```
df.head()
```

```
df.info()
```

```
df.isnull().sum()
```

```
df.duplicated().sum()
```

```
df.describe([x*0.1 for x in range(10)])
```

```
for c in list(df):
```

```
    print(df[c].value_counts())
```

# Data Quality: Why Preprocess the Data?

---

- Measures for data quality: A multidimensional view
  - Accuracy: correct or wrong, accurate or not
  - Completeness: not recorded, unavailable, ...
  - Consistency: some modified but some not, dangling, ...
  - Timeliness: timely update?
  - Believability: how trustable the data are correct?
  - Interpretability: how easily the data can be understood?

# Major Tasks in Data Preprocessing

---

- **Data cleaning**
  - Fill in missing values, smooth noisy data, identify or remove outliers, and resolve inconsistencies
- **Data integration**
  - Integration of multiple databases, data cubes, or files
- **Data reduction**
  - Dimensionality reduction
  - Numerosity reduction
  - Data compression

- Data Reduction
- Data Transformation and Data Discretization
- Summary

# Data Cleaning

---

- Data in the Real World Is Dirty: Lots of potentially incorrect data, e.g., instrument faulty, human or computer error, transmission error
  - incomplete: lacking attribute values, lacking certain attributes of interest, or containing only aggregate data
    - e.g., *Occupation*=" " (missing data)
  - noisy: containing noise, errors, or outliers
    - e.g., *Salary*="−10" (an error)
  - inconsistent: containing discrepancies in codes or names, e.g.,
    - *Age*="42", *Birthday*="03/07/2010"
    - Was rating "1, 2, 3", now rating "A, B, C"
    - discrepancy between duplicate records
  - Intentional (e.g., *disguised missing data*)
    - Jan. 1 as everyone's birthday?

# Incomplete (Missing) Data

---

- Data is not always available
  - E.g., many tuples have no recorded value for several attributes, such as customer income in sales data
- Missing data may be due to
  - equipment malfunction
  - inconsistent with other recorded data and thus deleted
  - data not entered due to misunderstanding
  - certain data may not be considered important at the time of entry
  - not register history or changes of the data
- Missing data may need to be inferred

# How to Handle Missing Data?

---

- Ignore the tuple: usually done when class label is missing (when doing classification)—not effective when the % of missing values per attribute varies considerably
- Fill in the missing value manually: tedious + infeasible?
- Fill in it automatically with
  - a global constant : e.g., “unknown”, a new class?!
  - the attribute mean
  - the attribute mean for all samples belonging to the same class: smarter
  - the most probable value: inference-based such as Bayesian formula or decision tree

# Noisy Data

---

- **Noise**: random error or variance in a measured variable
- **Incorrect attribute values** may be due to
  - faulty data collection instruments
  - data entry problems
  - data transmission problems
  - technology limitation
  - inconsistency in naming convention
- **Other data problems** which require data cleaning
  - duplicate records
  - incomplete data
  - inconsistent data

# How to Handle Noisy Data?

---

- Binning
  - first sort data and partition into (equal-frequency) bins
  - then one can smooth by bin means, smooth by bin median, smooth by bin boundaries, etc.
- Regression
  - smooth by fitting the data into regression functions
- Clustering
  - detect and remove outliers
- Combined computer and human inspection
  - detect suspicious values and check by human (e.g., deal with possible outliers)

# Data Cleaning as a Process

---

- Data discrepancy detection
  - Use metadata (e.g., domain, range, dependency, distribution)
  - Check field overloading
  - Check uniqueness rule, consecutive rule and null rule
  - Use commercial tools
    - Data scrubbing: use simple domain knowledge (e.g., postal code, spell-check) to detect errors and make corrections
    - Data auditing: by analyzing data to discover rules and relationship to detect violators (e.g., correlation and clustering to find outliers)
- Data migration and integration
  - Data migration tools: allow transformations to be specified
  - ETL (Extraction/Transformation/Loading) tools: allow users to specify transformations through a graphical user interface
- Integration of the two processes
  - Iterative and interactive (e.g., Potter's Wheels)

# Data Preprocessing

---

- Data Preprocessing: An Overview
  - Data Quality
  - Major Tasks in Data Preprocessing
- Data Cleaning
- **Data Integration**
- Data Reduction
- Data Transformation and Data Discretization
- Summary

# Data Integration

---

- **Data integration:**
  - Combines data from multiple sources into a coherent store
- Schema integration: e.g., A.cust-id  $\equiv$  B.cust-#
  - Integrate metadata from different sources
- **Entity identification problem:**
  - Identify real world entities from multiple data sources, e.g.,  
Bill Clinton = William Clinton
- Detecting and resolving data value conflicts
  - For the same real world entity, attribute values from different sources are different
  - Possible reasons: different representations, different scales, e.g., metric vs. British units

# Handling Redundancy in Data Integration

---

- Redundant data occur often when integration of multiple databases
  - *Object identification*: The same attribute or object may have different names in different databases
  - *Derivable data*: One attribute may be a “derived” attribute in another table, e.g., annual revenue
- Redundant attributes may be able to be detected by *correlation analysis* and *covariance analysis*
- Careful integration of the data from multiple sources may help reduce/avoid redundancies and inconsistencies and improve mining speed and quality

# Correlation

---

It indicates the degree to which two variables are related to each other .

It ranges from -1 to 1 in which -1 indicates the perfect negative correlation, zero indicates no correlation and +1 indicates perfectly positive correlation.

It can be calculated using different methods like Pearson Correlation Coefficient, Spearman Rank Correlation, Partial Correlation etc.

# Correlation Analysis (Nominal Data)

---

- **$\chi^2$  (chi-square) test**

$$\chi^2 = \sum \frac{(\textit{Observed} - \textit{Expected})^2}{\textit{Expected}}$$

- The larger the  $\chi^2$  value, the more likely the variables are related
- The cells that contribute the most to the  $\chi^2$  value are those whose actual count is very different from the expected count
- Correlation does not imply causality
  - # of hospitals and # of car-theft in a city are correlated
  - Both are causally linked to the third variable: population

# Visually Evaluating Correlation

**Scatter plots showing the similarity from -1 to 1.**

# Co-Variance

---

It is the measure of joint variability between two variable.

A positive co-variance indicates both vary in same direction whereas negative indicates both are in opposite direction.

Unlike correlation, co-variance is not normalized so it would be difficult to interpret the magnitude of value.

Methods for co-variance can be sample Co-variance, population covariance, Matrix Representation.

# Covariance (Numeric Data)

- Covariance is similar to correlation

$$Cov(A, B) = E((A - \bar{A})(B - \bar{B})) = \frac{\sum_{i=1}^n (a_i - \bar{A})(b_i - \bar{B})}{n}$$

Correlation coefficient:  $r_{A,B} = \frac{Cov(A, B)}{\sigma_A \sigma_B}$

where  $n$  is the number of tuples,  $\bar{A}$  and  $\bar{B}$  are the respective mean or **expected values** of  $A$  and  $B$ ,  $\sigma_A$  and  $\sigma_B$  are the respective standard deviation of  $A$  and  $B$ .

- **Positive covariance:** If  $Cov_{A,B} > 0$ , then  $A$  and  $B$  both tend to be larger than their expected values.
- **Negative covariance:** If  $Cov_{A,B} < 0$  then if  $A$  is larger than its expected value,  $B$  is likely to be smaller than its expected value.
- **Independence:**  $Cov_{A,B} = 0$  but the converse is not true:
  - Some pairs of random variables may have a covariance of 0 but are not independent. Only under some additional assumptions (e.g., the data follow multivariate normal distributions) does a covariance of 0 imply independence

# Data Preprocessing

---

- Data Preprocessing: An Overview
  - Data Quality
  - Major Tasks in Data Preprocessing
- Data Cleaning
- Data Integration
- **Data Reduction**
- Data Transformation and Data Discretization
- Summary

# Data Reduction Strategies

---

- **Data reduction:** Obtain a reduced representation of the data set that is much smaller in volume but yet produces the same (or almost the same) analytical results
- Why data reduction? — A database/data warehouse may store terabytes of data. Complex data analysis may take a very long time to run on the complete data set.
- Data reduction strategies
  - **Dimensionality reduction**, e.g., remove unimportant attributes
    - Wavelet transforms
    - Principal Components Analysis (PCA)
    - Feature subset selection, feature creation
  - **Numerosity reduction** (some simply call it: Data Reduction)
    - Regression and Log-Linear Models
    - Histograms, clustering, sampling
    - Data cube aggregation
  - **Data compression**

# Data Reduction 1: Dimensionality Reduction

- **Curse of dimensionality**
  - When dimensionality increases, data becomes increasingly sparse
  - Density and distance between points, which is critical to clustering, outlier analysis, becomes less meaningful
  - The possible combinations of subspaces will grow exponentially
- **Dimensionality reduction**
  - Avoid the curse of dimensionality
  - Help eliminate irrelevant features and reduce noise
  - Reduce time and space required in data mining
  - Allow easier visualization
- **Dimensionality reduction techniques**
  - Wavelet transforms
  - Principal Component Analysis
  - Supervised and nonlinear techniques (e.g., feature selection)

# Mapping Data to a New Space

- **Fourier transform**
- **Wavelet transform**

**Two Sine Waves**

**Two Sine Waves + Noise**

**Frequency**

# What Is Wavelet Transform?

- Decomposes a signal into different frequency subbands
  - Applicable to n-dimensional signals
- Data are transformed to preserve relative distance between objects at different levels of resolution
- Allow natural clusters to become more distinguishable

# Wavelet Transformation

- Discrete wavelet transform (DWT) for linear signal processing, multi-resolution analysis
- Compressed approximation: store only a small fraction of the strongest of the wavelet coefficients
- Similar to discrete Fourier transform (DFT), but better lossy compression, localized in space
- Method:
  - Length,  $L$ , must be an integer power of 2 (padding with 0's, when necessary)
  - Each transform has 2 functions: smoothing, difference
  - Applies to pairs of data, resulting in two set of data of length  $L/2$
  - Applies two functions recursively, until reaches the

# Principal Component Analysis (PCA)

- Find a projection that captures the largest amount of variation in data
- The original data are projected onto a much smaller space, resulting in dimensionality reduction. We find the eigenvectors of the covariance matrix, and these eigenvectors define the new space

# Principal Component Analysis (Steps)

---

- Given  $N$  data vectors from  $n$ -dimensions, find  $k \leq n$  orthogonal vectors (*principal components*) that can be best used to represent data
  - Normalize input data: Each attribute falls within the same range
  - Compute  $k$  orthonormal (unit) vectors, i.e., *principal components*
  - Each input data (vector) is a linear combination of the  $k$  principal component vectors
  - The principal components are sorted in order of decreasing “significance” or strength
  - Since the components are sorted, the size of the data can be reduced by eliminating the *weak components*, i.e., those with low variance (i.e., using the strongest principal

# Attribute Subset Selection

---

- Another way to reduce dimensionality of data
- Redundant attributes
  - Duplicate much or all of the information contained in one or more other attributes
  - E.g., purchase price of a product and the amount of sales tax paid
- Irrelevant attributes
  - Contain no information that is useful for the data mining task at hand
  - E.g., students' ID is often irrelevant to the task of predicting students' GPA

# Heuristic Search in Attribute Selection

---

- There are  $2^d$  possible attribute combinations of  $d$  attributes
- Typical heuristic attribute selection methods:
  - Best single attribute under the attribute independence assumption: choose by significance tests
  - Best step-wise feature selection:
    - The best single-attribute is picked first
    - Then next best attribute condition to the first, ...
  - Step-wise attribute elimination:
    - Repeatedly eliminate the worst attribute
  - Best combined attribute selection and elimination

# Parametric Data Reduction: Regression and Log-Linear Models

---

- **Linear regression**
  - Data modeled to fit a straight line
  - Often uses the least-square method to fit the line
- **Multiple regression**
  - Allows a response variable  $Y$  to be modeled as a linear function of multidimensional feature vector
- **Log-linear model**
  - Approximates discrete multidimensional probability distributions

# Regression Analysis

- Regression analysis: A collective name for techniques for the modeling and analysis of numerical data consisting of values of a **dependent variable** (also called **response variable** or *measurement*) and of one or more *independent variables* (aka. **explanatory variables** or **predictors**)
- The parameters are estimated so as to give a "**best fit**" of the data
- Most commonly the best fit is evaluated by using the **least squares method**, but other criteria

- Used for prediction (including forecasting of time-series data), inference, hypothesis testing, and modeling of causal relationships

# Histogram Analysis

- Divide data into buckets and store average (sum) for each bucket
- Partitioning rules:
  - Equal-width: equal bucket range
  - Equal-frequency (or equal-depth)

# Clustering

---

- Partition data set into clusters based on similarity, and store cluster representation (e.g., centroid and diameter) only
- Can be very effective if data is clustered but not if data is “smeared”
- Can have hierarchical clustering and be stored in multi-dimensional index tree structures
- There are many choices of clustering definitions and clustering algorithms

# Sampling

---

- Sampling: obtaining a small sample  $s$  to represent the whole data set  $N$
- Allow a mining algorithm to run in complexity that is potentially sub-linear to the size of the data
- Key principle: Choose a **representative** subset of the data
  - Simple random sampling may have very poor performance in the presence of skew
  - Develop adaptive sampling methods, e.g., stratified sampling:
- Note: Sampling may not reduce database I/Os

# Types of Sampling

---

- **Simple random sampling**
  - There is an equal probability of selecting any particular item
- **Sampling without replacement**
  - Once an object is selected, it is removed from the population
- **Sampling with replacement**
  - A selected object is not removed from the population
- **Stratified sampling:**
  - Partition the data set, and draw samples from each partition (proportionally, i.e., approximately the same percentage of the data)
  - Used in conjunction with skewed data

# Sampling: With or without Replacement

# Sampling: Cluster or Stratified Sampling

Raw Data

Cluster/Stratified Sample

# Data Cube Aggregation

---

- The lowest level of a data cube (base cuboid)
  - The aggregated data for an **individual entity of interest**
  - E.g., a customer in a phone calling data warehouse
- Multiple levels of aggregation in data cubes
  - Further reduce the size of data to deal with
- Reference appropriate levels
  - Use the smallest representation which is enough to solve the task
- Queries regarding aggregated information should

# Data Reduction 3: Data Compression

---

- String compression
  - There are extensive theories and well-tuned algorithms
  - Typically lossless, but only limited manipulation is possible without expansion
- Audio/video compression
  - Typically lossy compression, with progressive refinement
  - Sometimes small fragments of signal can be reconstructed without reconstructing the whole
- Time sequence is not audio
  - Typically short and vary slowly with time
- Dimensionality and numerosity reduction may also

# Data Compression

---

# Data Preprocessing

---

- Data Preprocessing: An Overview
  - Data Quality
  - Major Tasks in Data Preprocessing
- Data Cleaning
- Data Integration
- Data Reduction
- **Data Transformation and Data Discretization**
- Summary

# Data Transformation

---

- A function that maps the entire set of values of a given attribute to a new set of replacement values s.t. each old value can be identified with one of the new values
- Methods
  - Smoothing: Remove noise from data
  - Attribute/feature construction
    - New attributes constructed from the given ones
  - Aggregation: Summarization, data cube construction
  - Normalization: Scaled to fall within a smaller, specified range
    - min-max normalization
    - z-score normalization
    - normalization by decimal scaling

# Normalization

- **Min-max normalization:** to  $[\text{new\_min}_A, \text{new\_max}_A]$

$$v' = \frac{v - \min A}{\max A - \min A} (\text{new}_{\max} A - \text{new}_{\min} A) + \text{new}_{\min} A$$

- Ex. Let income range \$12,000 to \$98,000 normalized to [0.0, 1.0]. Then \$73,000 is mapped to  $\frac{73,000 - 12,000}{98,000 - 12,000} (1.0 - 0) + 0 = 0.716$

- **Z-score normalization** ( $\mu$ : mean,  $\sigma$ : standard deviation):

$$v' = \frac{v - \mu A}{\sigma A}$$

- Ex. Let  $\mu = 54,000$ ,  $\sigma = 16,000$ . Then  $\frac{73,000 - 54,000}{16,000} = 1.225$

- **Normalization by decimal scaling**

$$v' = \frac{v}{10^j} \quad \text{Where } j \text{ is the smallest integer such that } \text{Max}(|v'|) < 1$$

# Discretization

---

- Three types of attributes
  - Nominal—values from an unordered set, e.g., color, profession
  - Ordinal—values from an ordered set, e.g., military or academic rank
  - Numeric—real numbers, e.g., integer or real numbers
- Discretization: Divide the range of a continuous attribute into intervals
  - Interval labels can then be used to replace actual data values
  - Reduce data size by discretization
  - Supervised vs. unsupervised
  - Split (top-down) vs. merge (bottom-up)

# Data Discretization Methods

---

- Typical methods: All the methods can be applied recursively
  - **Binning**
    - Top-down split, unsupervised
  - **Histogram analysis**
    - Top-down split, unsupervised
  - **Clustering analysis** (unsupervised, top-down split or bottom-up merge)
  - **Decision-tree analysis** (supervised, top-down split)
  - **Correlation (e.g.,  $\chi^2$ ) analysis** (unsupervised,

# Simple Discretization: Binning

---

- **Equal-width** (distance) partitioning
  - Divides the range into  $N$  intervals of equal size: uniform grid
  - if  $A$  and  $B$  are the lowest and highest values of the attribute, the width of intervals will be:  $W = (B - A)/N$ .
  - The most straightforward, but outliers may dominate presentation
  - Skewed data is not handled well
- **Equal-depth** (frequency) partitioning
  - Divides the range into  $N$  intervals, each containing approximately same number of samples
  - Good data scaling

# Data Preprocessing

---

- Data Preprocessing: An Overview
  - Data Quality
  - Major Tasks in Data Preprocessing
- Data Cleaning
- Data Integration
- Data Reduction
- Data Transformation and Data Discretization
- **Summary**

# Summary

---

- **Data quality:** accuracy, completeness, consistency, timeliness, believability, interpretability
- **Data cleaning:** e.g. missing/noisy values, outliers
- **Data integration** from multiple sources:
  - Entity identification problem
  - Remove redundancies
  - Detect inconsistencies
- **Data reduction**
  - Dimensionality reduction
  - Numerosity reduction
  - Data compression
- **Data transformation and data discretization**
  - Normalization
